Executive Summary

The hydrologic and hydraulic analysis described herein evaluates design alternatives for a drainage system for the area interior to the Smith Island Estuary Restoration project setback dike in Snohomish County, Washington. The Smith Island Estuary Restoration project includes the construction of a setback dike, and breaching of an existing dike along Union Slough, which is a tributary to the Snohomish River and is tidally influenced by Puget Sound. The interior area of Smith Island is at a relatively low elevation and exhibits relatively high groundwater levels through much of the year due to inflow from the adjacent Union Slough, the nearby Snohomish River, rainfall, as well as coastal waters. The land use of much of the island is currently fallow pasture with areas of freshwater wetlands, and areas interior to the proposed setback dike alignment are used for agriculture.

The alignment of the setback dike is within Snohomish County property, and the interior land uses include a tree nursery business located on the opposite side of a remnant tidal channel from the setback dike. The tree nursery's drain tiles outlet to the tidal channel, and high surface water in the channel can interfere with adequate drainage of the nursery property. Drainage improvements will be constructed as a part of the Smith Island Estuary Restoration project to manage the stormwater runoff from the interior area of the setback dike so that property owners are not adversely impacted. The proposed drainage improvements include a drainage pond and culvert to drain the existing tidal channel (West Tidal Channel) and maintain low water surface elevations to avoid impacting the nursery operation. The drainage pond will outlet to Union Slough, but it can only drain when the water levels in the slough are lower than the level in the pond without the addition of a pump station.

The soils, land uses, and existing flow patterns of the area were identified for the area interior to the dike, and were used to develop the simulation of the hydrologic response under the proposed conditions of a setback dike and drainage system. The drainage system consists of a drainage pond that will drain the tidal channel next to the tree nursery property, with several design alternatives evaluated for the pond outlet. The following alternatives are considered for draining the pond: 1) one gravity outlet, 2) two gravity outlets, 3) a pump station with a total outflow of two cubic feet per second (cfs) and two gravity outlets, or 4) a pump station with a total outflow of four cfs (presumably two 2-cfs pumps) and two gravity outlets. The drainage analysis for the study area includes conservative assumptions in the simulation of stages for Union Slough based on Snohomish River data, seepage rates into the system from nearby groundwater sources (determined by Shannon and Wilson, October 2013, Appendix F), and surface runoff from saturated soil conditions to determine surface water levels within the tidal channel and drainage pond for the approximately 60-year period of record of rainfall data.

The results from the drainage analysis indicate that the use of two gravity outlets for the pond significantly reduces water elevations during the simulation, but the stage on Union Slough restricts gravity drainage to low stage windows. The limited duration of the low tide and river stage window does not allow a gravity drainage system to reliably maintain surface water levels lower than the relatively low tile drain inverts based on seepage inflow from nearby subsurface sources and rainfall

Executive Summary

Continued

on periodically-inundated soils. The time periods when drainage of the pond is critical tends to coincide with higher stages on Union Slough, when gravity drainage will not occur.

The water surface elevations in the tidal channel can be managed by regulating the elevations in the drainage pond because a culvert connects the channel to the pond. When a pump system with a total output of two cfs is operated as a contingency measure, the simulation indicates that when the pump station is set to turn on when water surface elevations are near the tile drain inverts, the two cfs flow rate provides the capacity necessary to maintain surface water below the tile drains for most conditions, but not the largest flood events. The addition of a second two-cfs pump to produce a four-cfs capacity pump system drains the drainage pond system faster and maintains a lower peak water surface elevation in the channel during the large flood events. The additional two-cfs pump does not provide significant benefit for the more frequent conditions and operation.

Section I—Introduction

This report presents the results of the hydrologic and hydraulic modeling for the area interior to the proposed Smith Island Estuary Restoration Project setback dike in Snohomish County, Washington. The purpose of this effort is to determine the surface runoff conditions of the area interior to the proposed setback dike (the study area) in order to design the interior drainage facilities to serve the property owners located landward of the proposed setback dike.

An initial interior drainage modeling study conducted by TetraTech (May 2013A) to support the Smith Island Restoration Project Environmental Impact Statement (EIS) was reviewed and the hydrologic and hydraulic modeling described herein was developed based on updated design features of the Smith Island setback dike. Additionally, Shannon & Wilson and Snohomish County evaluated groundwater and seepage conditions and their impact on the dike design and interior drainage (Shannon and Wilson, October 2013, Appendix F) and these results are included in this modeling study. All elevation data were collected relative to North American Vertical Datum 1988 (NAVD88).

Project Description

Smith Island is located in Snohomish County, Washington, adjacent to the City of Everett, on the west side of Union Slough and east of the Snohomish River within Sections 9 and 10 of Township 29 and Range 5 (Figure 1). The objective of the Snohomish County Smith Island Estuary Restoration Project is to restore critical habitat for salmonids and other native aquatic species in the Snohomish River basin by constructing a setback dike and breaching an existing dike to restore tidal influence to approximately 340 acres of the Snohomish River estuary.

The proposed setback dike will extend from the existing dike along Union Slough, through the former agriculture land between the East and West Tidal Channels, across 12th Street NE, and connect to the dike on the north side of the City of Everett's Water Pollution Control Facility (Figure 1). The proposed setback dike will be built to an elevation of 15 feet (NAVD88). The existing dike along Union Slough ranges in top elevation from approximately 12 to 14 feet from the connection with the setback dike to Interstate 5 (I-5). The elevation of the dike around the City of Everett's Water Pollution Control Facility (WPCF) is 15 feet (NAVD88). The elevation of the proposed setback dike provides more than two feet of freeboard above the 10-year flood elevation. The elevation of 15 feet is the 100-year base flood elevation for this area.

The Smith Island Estuary Restoration project area includes the dike footprint and access roads, County-owned property on the interior area (west side) of the dike, as well as the restoration area on the east side of the dike. The study area for the hydrologic and hydraulic analyses described herein consists of County and privately-owned property on the interior area (west side of the dike) that will drain to the drainage conveyance system under the proposed project conditions. The hydrologic and hydraulic study area extends from Union Slough at the north end to 12th Street NE at the south end, and from the setback dike at the east end to I-5 on the west end. The project area south of

Section I—Introduction

Continued

12th Street NE is not included in this study because it is within the City of Everett and they will evaluate their requirements for interior drainage on their property.

The study area currently drains to Union Slough through the East and West Tidal Channels, and to the Snohomish River through the Southwest Tidal Channel. In previous reports by others, the East, West, and Southwest Tidal Channels have been referred to as Tidal Channels A, B, and C, respectively.

Section 2—Existing Drainage Conditions

Land Use

The land use of the 130-acre study area is primarily agricultural in nature. Most of the study area has been a tree nursery for the past 10 years or more. Currently Hima Farms operates a tree nursery on approximately 70 acres in the northern portion of the study area. There is a portion between the Hima Farms operation and Union Slough that has been pasture grass for more than 10 years. The southern third of the study area is mostly pasture for horses under the care of Snohomish County. There is a caretaker's house, and several barns and sheds that serve the horse farm. There are trailers and various temporary facilities that serve Hima Farm's tree nursery operation. Gravel and dirt roads cross the study area. One gravel road serves as a frontage road to I-5, while another gravel road divides the tree farm operation from the horse farm. The tree farm has other gravel roads to serve its operations. Dirt roads provide access to the various pastures on the horse farm. The remnant tidal channels, and open ditches, such as those along the toe of the existing dike, are classified as open water and have saturated conditions throughout the year.

The 12th Street NE public access road is aligned in an east-west direction at the southern border of the study area and the border between Snohomish County and the City of Everett jurisdictions. The Puget Sound Energy (PSE) underground natural gas pipeline crosses the southern portion of the study area approximately 75 feet north of 12th Street NE. The area south of 12th Street NE is owned by the City of Everett and includes the Everett Water Pollution Control Facility. The project area south of 12th Street NE is not included in this study because it is within the City of Everett and they will evaluate their requirements for interior drainage on their property.

Soil Types

The study area consists primarily of silty clay loam that has been formed by floodplain alluvium material, and is high-quality farmland when drained. The USDA Natural Resource Conservation Service (NRCS) has mapped the soils of the study area as generally Puget silty clay loam or Snohomish silt loam soil types (Figure 2). It is assumed that the soil types have been modified by soil amendments and agricultural practices within the tree nursery property. The areas of the project site south of the Hima Nursery and north of the 12th Street NE alignment consist of Category II Freshwater Wetlands, and are inundated with surface water in depressions during winter months based on site reconnaissance.

The project geotechnical report found that estuarine deposits were the primary near-surface soil type on the site (Shannon and Wilson, October 2013). The estuarine soils are described as “soft, organic silt and clayey silt with abundant organics and scattered peat layers” to a depth of about four to eight feet. Alluvial deposits were discovered in some borings underlying the estuarine deposits and are described as “very loose to dense, trace of silt to silty sand.” According to the National Resources Conservation Service (NRCS), these soils can generally be classified as belonging to hydrologic soil group (HSG) C.

Section 2—Existing Drainage Conditions

Continued

Drainage Features

The West Tidal Channel (Photos 1 and 2) has been separated into two sections by a field crossing near the northeastern corner of the Hima Farms tree nursery property, and the nursery operation pumps water from the southern portion of the West Tidal Channel over the earthen field crossing to the north portion of the channel to maintain water surface elevations below the drainage tile inverts (Photo 3), which were surveyed by Snohomish County (Appendix A). Surface water in the West Tidal Channel north of the earthen field crossing is connected to a 48-inch CMP under I-5. As of August 2013, the 48-inch CMP culvert is partially obstructed by accumulated sediment and debris.

Photo 1.
The West Tidal Channel looking South from approximately Station 33+00 of the proposed setback dike in February 2013.

An east-west ditch is connected by 12-inch diameter pipes and a gate valve to the West Tidal Channel and the East Tidal Channel (Appendix B). The 12-inch pipe from the West Tidal Channel into the ditch has an invert elevation of -1.43 feet on the west end, and -1.24 feet on the east side based on field survey. The ditch contains ponded water through much of the year.

Photo 2.
The northern end of the West Tidal Channel looking northwest from the earthen field crossing at approximately Station 55+00 of the proposed setback dike in February 2013.

Interstate-5 Roadway Drainage

The drainage of I-5, the western boundary of the study area, was determined by a review of Washington Department of Transportation as-built drawings (WSDOT, 1990), Light Detection and Ranging (LiDAR) topographic data, and field reconnaissance (June 2013). I-5 roadway corridor is crowned along most of the study area such that the northbound lanes drain eastward into the study area and the southbound lanes drain to the west. The I-5 roadway is superelevated to the west through a slight curve approximately 1,600 feet south of the bridge over Union Slough. Within this superelevated portion of I-5, a 1,200-foot section of the northbound lanes drain westward into a series of catch basins located in the median. These catch basins all drain to the west side of I-5 per the 1990 WSDOT as-built drawings.

Section 2—Existing Drainage Conditions

Continued

Existing Conditions Sub-basin Delineation

Five sub-basins were delineated within the study area for the existing conditions (Figure 3). The sub-basin boundaries were determined by an analysis of surface topography and the drainage direction of ditches, culverts, and drain tile pipes located throughout the site and field verified by site reconnaissance during spring and summer of 2013. Surface topography was established by Snohomish County LiDAR elevation data and topographic surveys by Snohomish County throughout the study area. The elevation and location of ditches, culverts, and drain tile pipe inverts were also established by surveys conducted by Snohomish County.

Photo 3.

One of the drain tiles conveying irrigation and runoff water from the tree nursery operation to the West Tidal Channel in February 2013.

Sub-basin E1

Sub-basin E1 consists of a significant portion of the Snohomish County-owned property within the study area and the restoration area east of the dike, which drains to the East Tidal Channel under existing conditions. The sub-basin E-1 drainage area consists primarily of undeveloped, fallow pasture, open space, and water features such as the tidal channels and remnant agricultural ditches. In addition, a short segment of I-5 near Union Slough drains into sub-basin E1 in the current condition. The existing grade typically ranges between four to five feet elevation within the sub-basin, except for the tidal channel and ditch bottoms which have elevations as low as approximately -3.0 feet at some locations. The ditches typically contain ponded water throughout the year, and do not necessarily drain to the East Tidal Channel during portions of the year due to the relatively flat topography. The boundaries for sub-basin E1 were delineated based on surface topography and identification of ditches that are likely to drain to the East Tidal Channel. Also, a portion of the area in sub-basin E1 south of the tree nursery property may drain to the Southwest Tidal Channel; however, the area is assumed to drain to the east as a conservative assumption so that it is routed into the proposed drainage system for design calculations under the proposed conditions.

The sub-basin E1 drainage area is modified under the proposed conditions by the setback dike alignment, which partitions the drainage area west of the dike to flow into the drainage conveyance system and out to Union Slough, and the remaining area east of the setback dike alignment will continue to flow to the East Tidal Channel.

Section 2—Existing Drainage Conditions

Continued

Sub-basin E2

Sub-basin E2 includes areas of the tree nursery property, and is bounded by the east bank of the West Tidal Channel at the sub-basin's eastern edge, and a surface drainage divide along the tree nursery property line to the south. The western and northern boundaries of sub-basin E2 have been defined by the extent of subsurface drain tiles located throughout the property. The location and orientation of the drain tile pipes have been determined based on field reconnaissance, survey (Appendix A), personal communication (A-1 Landscaping, September 2013), as well as drawings from the Snohomish Conservation District (March 2011). In the northern portion of the tree nursery property, drain tile pipes run north-south and drain to a ditch in the center of the tree nursery property. The ditch connects to the West Tidal Channel through an 18-inch polyvinyl chloride (PVC) pipe to the east and connects to a ditch along the western edge of the tree nursery property by a 24-inch pipe with a manually-operated gate. In the southern portion of the tree nursery property, drain tile pipes run east-west and discharge to both the east and west sides of the tree nursery property. On the east side, the drain tile pipes discharge directly into the West Tidal Channel.

Sub-basin E3

Sub-basin E3 is the southwestern area of the tree nursery property. It is bounded by the crown of I-5 to the west, and the extents of drain tiles to the south, east, and north. Runoff flows to a ditch along the west property line of the tree nursery. A 24-inch CMP with a flap gate and invert elevation of 0.61 feet allows gravity drainage from the western ditch into the Southwest Tidal Channel; however, this elevation is above the drain tile inverts of the tree nursery (the lowest tile drain invert is -0.60 feet, Appendix A). A pump station is operated under existing conditions to move stormwater from the western ditch to the south into the Southwest Tidal Channel to maintain low water surface elevations within the ditch.

Sub-basin E4

Sub-basin E4 is the County-owned property that drains to the Southwest Tidal Channel which drains under I-5 through a 30-inch culvert with an invert elevation of 0.48 feet. The drainage area is bounded by the crown of I-5 to the west, the crown of 12th Street NE to the south, and surface drainage divides to the north and east of the Southwest Tidal Channel. Portions of the sub-basin E1 area may drain into the Southwest Tidal Channel, but have been assumed to drain east as a conservative assumption for designing the drainage system for the proposed conditions.

Sub-basin E5

Sub-basin E5 is the area draining to the ditch along I-5 and the northern section of the West Tidal Channel that is disconnected from the southern section of the West Tidal Channel by an earthen field crossing. Sub-basin E5 is bounded by the crown of I-5 to the west, an access road into the tree nursery to the south, the field crossing and surface divides to the east and north. The disconnected section of the West Tidal Channel drains west into the ditch through a CMP with a rusted out bottom and a top elevation of -1.53 feet. The ditch at the toe of the I-5 embankment collects runoff from a segment of I-5 and the disconnected section of the West Tidal Channel and drains off-site under I-5 through a 48-inch CMP, which is partially clogged by sediment and debris as of August 2013. The maintenance of this culvert is not within Snohomish County jurisdiction.

Section 3—Proposed Drainage Conditions

Drainage Improvements

Drainage improvements will be constructed to manage the stormwater runoff from the study area so that property owners are not adversely impacted. The drainage improvements include:

- A 36-inch diameter pipe with tide gate to replace the existing culvert with tide gate that outfalls to Union Slough
- A drainage pond with approximately 38 acre-feet of live storage to compensate for the loss of storage currently provided by the East Tidal Channel
- A 36-inch diameter pipe to connect the West Tidal Channel to the drainage pond including a flap gate to prevent the backflow from the pond to the tidal channel
- A toe ditch to convey seepage from the setback dike to the drainage pond, with a pipe and flapgate preventing backflow from the pond into the ditch.
- A pump station to provide additional capability for Hima Farms to maintain low water levels in the West Tidal Channel adjacent to their nursery
- A 36-inch diameter pipe with tide gate to provide a secondary outlet from the West Tidal Channel
- A 36-inch diameter culvert that will connect the toe ditch along the existing dike (that remains as it is) to the drainage pond

Proposed Conditions Sub-basin Delineation

Eight sub-basins were delineated within the study area for the proposed conditions on the landward side of the setback dike (Figure 4). As described for the existing conditions delineation, sub-basin boundaries were determined by survey of surface topography, ditches, culverts, and drain tiles.

The location of the setback dike modifies the existing condition sub-basin E1 (Figure 3) so that areas interior to the dike drain to the drainage pond or the West Tidal Channel. The additional areas assuming to drain to the West Tidal Channel are shown in Figure 4 as proposed conditions sub-basins 3 and 5 (P3 and P5). Proposed sub-basins 1 and 2 (P1 and P2) drain to the drainage pond under proposed conditions, instead of the East Tidal Channel. The remaining proposed conditions sub-basins (P4, P6, P7, P8) remain unchanged from the existing conditions.

Document Path: K:\project\311800\311852A\GIS\MXDs\Figures\FORDaveS_version2\Figure4\ProposedConditions.mxd

Section 3—Proposed Drainage Conditions

Continued

Sub-basin P1

Sub-basin P1 is bounded by the top of the existing dike to the north and east, the crown of I-5 to the west, and a surface drainage divide to the south. Runoff is collected in an existing ditch located along the landward toe of the existing dike and is conveyed to the proposed pond through a proposed 36-inch Corrugated Polyethylene Pipe (CPEP) culvert.

Sub-basin P2

Sub-basin P2 is bounded by a surface drainage divide to the north, the top of the proposed setback dike to the east, a surface drainage divide along the West Tidal Channel to the south, and the crown and edge of I-5 to the west. I-5 is superelevated for approximately 1,200 feet at the western boundary near the 48-inch CMP culvert crossing. This portion of I-5 drains to catch basins located in the I-5 median which discharge to the west through storm drain pipes. North of the superelevated portion of I-5, 480 feet of northbound I-5 sheet flows east to the study area. Sub-basin P2 drains by surface flow to the drainage pond.

Sub-basin P3

Sub-basin P3 is bounded by the setback dike to the east and a surface drainage divide that runs along the West Tidal Channel to the west, and drains to the West Tidal Channel by surface flow. The toe ditch is located within sub-basin P3, but the toe ditch is assumed not to capture any surface flow from sub-basin P3 or seepage into the West Tidal Channel as a conservative assumption.

Sub-basin P4

Sub-basin P4 includes the majority of the tree nursery property, and the drainage boundaries and characteristics of sub-basin P4 will not be affected under proposed conditions and has the same extents as sub-basin E2.

Sub-basin P5

Sub-basin P5 is bounded by a surface drainage divide along the tree nursery property line to the north, the setback dike to the east, the crown of 12th Street NE to the south, and a surface drainage divide that runs along the east side of the Southwest Tidal Channel. This sub-basin is relatively flat with typical elevation ranging from four to five feet NAVD88 and surface depressions that do not drain during wetter months. The area shown as sub-basin P5 is assumed to drain to the West Tidal Channel and then to the proposed storage pond as a conservative measure, while some areas within sub-basin P5 may actually drain off-site to the Southwest Tidal Channel.

Areas of sub-basin P5 contain surface depressions and are classified as Category II Freshwater Wetlands (Photo 4). The storage volume of the surface depressions was calculated with CAD

Photo 4.
Looking northwest into proposed conditions sub-basin
area P5 in February 2013.

Section 3—Proposed Drainage Conditions

Continued

(Autodesk Civil 3D 2012) (Appendix C) to determine elevations where stormwater will drain north to the West Tidal Channel.

Sub-basin P6

Sub-basin P6 represents the area that drains off-site to the west through a 48-inch CMP under I-5. The drainage area includes a portion of northbound I-5 and the disconnected northern section of the West Tidal Channel. The drainage boundaries and characteristics of sub-basin P6 will not be affected by the proposed project and has the same extents as existing conditions sub-basin E5.

Sub-basin P7

Sub-basin P7 includes the southwestern portion of the tree nursery property and a 1,300-foot section of northbound I-5. The drainage boundaries and characteristics of sub-basin P7 are not affected under the proposed condition and are the same as existing conditions sub-basin E3.

A pump station operated by the tree nursery moves stormwater from the west ditch to the Southwest Tidal Channel in the current condition. If the pump station were not operating and water surface elevation increases within the western ditch, stormwater may enter the drain tile inverts on the western property edge (the lowest tile drain invert is -0.6 feet in elevation) and drain towards the channel on the eastern property edge (the West Tidal Channel, with drain tile invert elevations varying from -1.71 feet up to 1.75 feet (Appendix A). As a conservation assumption, the sub-basin P7 surface runoff is assumed to drain to the West Tidal Channel to represent conditions where the pump station is not operating.

Sub-basin P8

Sub-basin P8 includes the southwestern portion of the project site and an approximately 1,350-foot section of northbound I-5. The drainage boundaries and characteristics of sub-basin P8 are not affected in the proposed condition and drains off-site in existing conditions as described for sub-basin E4.

Section 4—Drainage Analysis Methods

The interior drainage analysis used the Western Washington Hydrology Model (WWHM) 2012 for hydrologic simulation and the U.S. Environmental Protection Agency Storm Water Management Model (EPA SWMM) Version 5.0 to simulate the hydraulics of the proposed drainage system. The proposed conditions were modeled to evaluate design alternatives for the drainage system and determine the water surface elevations within the West Tidal Channel. The existing conditions were not modeled as a part of this study because the existing peak discharges do not affect design and the Tidal Channel water surface elevations vary in the existing condition based on the pumping rates by the tree nursery.

WWHM Hydrologic Model

The Washington State Department of Ecology Western Washington Hydrology Model 2012 (WWHM) was used to determine the stormwater flow rates from the study area into the drainage system. WWHM is a continuous simulation hydrologic modeling software that provides an interface for using the Hydrological Simulation Program Fortran (HSPF) model algorithms developed by the U.S. Geological Survey and U.S. Environmental Protection Agency.

WWHM Model Input

The proposed conditions were modeled in WWHM to simulate inflow rates into the drainage system from the study area.

WWHM requires input data for precipitation, evaporation, and land use, surface slope, and soil classification. Meteorological inputs such as precipitation and evaporation are included within WWHM and are chosen by selecting the project site from a map interface. For the study area, precipitation data from water years 1948 to 2009 is used from the National Weather Service Everett precipitation gauge with a scaling factor of 1.00 applied. Evaporation is applied as a universal Pan Evaporation Factor of 0.76, a standard value used for WWHM modeling.

The land cover of the area within the proposed setback dike primarily consists of farmland, fallow pasture, and a small number of gravel access roads and minor structures. There is relatively little elevation change across the study area with the exception of short steep slopes along the dike embankment (proposed and existing) and the I-5 corridor embankment.

Saturated soil conditions (hydrologic soil group D) were used in the hydrologic model during the length of the simulation as a conservative assumption rather than soil types classified as group C due to the relatively high groundwater levels, the proximity of the study area to tidally influenced waterways, and relatively low infiltration rates are expected. The use of saturated soil conditions in the model results in a higher volume of runoff per unit of rainfall.

The land cover of the study area was modeled in WWHM as primarily flat pasture with saturated soils. The steep areas along the dike and I-5 corridor were measured and included in the model as steep pasture with saturated soils. The proposed and existing gravel and paved roads are included as impervious areas. These include the access road on the landward side of the dike, the dike top access road, the proposed gravel parking lot, the gravel roads within and adjacent to the tree nursery

Section 4—Drainage Analysis Methods

Continued

property, and portions of the northbound I-5 roadway and 12th Street NE roadway. The water surface area of the proposed pond, the West Tidal Channel, and the Southwest Tidal Channel are assigned the “Pond” impervious land cover type in WWHM and directly contribute runoff to the hydrograph time series.

WWHM is utilized to create a runoff time series from the interior basins. Sub-basin surface and interflow runoff time series are output at a 15-minute time step from October 1, 1948 to September 30, 2009. Sub-basins were created in the model to represent the combined outflow from Sub-basins P1 and P2 to the proposed pond, the combined outflow from sub-basins P3, P4, P5, and P7 to the segment of the West Tidal Channel connected to the drainage pond. In addition, runoff was modeled for the individual sub-basins for determination of peak discharges.

One Percent Annual Chance (100-year) Runoff Analysis

The One Percent Annual Chance (100-year) rainfall depths for varying durations from NOAA (1973) and the USDA Soil Conservation Service (1964) were compared to observed rainfall depths from the December 1996 storm. The 24-hour 100-year storm and the 1996 event were modeled and the event with more conservative runoff volumes was used to evaluate a 100-year or larger storm in the SWMM model.

SWMM Hydraulic Model

The U.S. Environmental Protection Agency’s Storm Water Management Model (EPA SWMM) Version 5 was created by the Water Supply and Water Resources Division of the EPA’s Risk Management Research program and is used to determine the hydraulic routing of runoff originating from the study area.

SWMM Model Input

Surface Runoff

The time series from the WWHM model were entered as inflow into the West Tidal Channel and the drainage pond for the simulation period from 1948 to 2009. The WWHM time series for P1 and P2 were entered as inflow to the drainage pond, and the time series from P3, P4, P5, and P7 were entered as inflow to the West Tidal Channel. The disconnected northern section of the West Tidal Channel will continue to drain off-site in the proposed conditions, and therefore, the storage associated with the disconnected northern section of the West Tidal Channel is not included in the SWMM model. Elevations entered into the SWMM model were converted to a datum of 100 feet to avoid conflicts within the computer application from using negative tidal stage elevations.

Tidal Channel and Drainage Pond Volumes

The section of the West Tidal Channel that will be connected to the drainage pond in the proposed condition is represented as a storage feature in the SWMM model. A stage-storage table was developed for the West Tidal Channel (Appendix C) based on LiDAR data and topographic survey data collected by Snohomish County. The volume of the West Tidal Channel was determined in 0.5-

Section 4—Drainage Analysis Methods

Continued

foot depth increments using CAD (Autodesk Civil 3D 2012). The calculated volume was reduced by 10 percent to account for the presence of vegetation, woody debris, and sediment accumulation in the West Tidal Channel. An equivalent area was calculated based on the storage volumes after the assumed 10 percent loss in storage (Appendix C) for entry into the SWMM model. The volume of the West Tidal Channel at an elevation of -0.6 feet is approximately 5.9 acre-feet for the section south of the field crossing. The southern section of the West Tidal Channel is connected to the proposed drainage pond with a 36-inch, culvert with the inlet and outlet inverts both equal to an elevation of -2.14 feet. An initial water surface elevation of -1.0 feet has been assumed as opposed to an initial ponded elevation of -2.14 feet as a conservative assumption to simulate a storm event preceding the model simulation.

A stage-storage table was developed for the drainage pond based on proposed site grading. CAD was used to determine the volume of the proposed pond at 1-foot increments. The calculated volumes were reduced by five percent to account for loss of storage due to vegetation, debris, and sediment deposition. The five percent loss of storage was assumed for the drainage pond because vegetation is expected to occupy a smaller percent of storage within the pond than what is expected in the West Tidal Channel. The deeper water depths within the pond are expected to inhibit growth of cattail or reed canary grass, the area of the pond is large relative to the perimeter where vegetation is likely to grow, and maintenance of vegetation and sediment is expected within the drainage pond. A stage-area table was developed from these reduced incremental volumes for use in SWMM. The proposed drainage pond has a live storage volume of approximately 37.4 acre-feet at an elevation of 3.0 feet. The proposed pond has one foot of dead storage, 3:1 sideslopes, and provides storage up to approximately three or four feet in elevation. The proposed drainage pond drains when the head exceeds that of the tidally-influenced Union Slough.

Culverts

Two 36-inch diameter culverts with tide gates will drain the West Tidal Channel and drainage pond system when the head in the system exceeds the tidally-influenced water surface elevation of Union Slough. One culvert will connect the West Tidal Channel to the East Tidal Channel near the approximate location of the existing agricultural ditch, and the other culvert will connect the drainage pond to Union Slough. The invert elevations of both culverts have been set at a constant -2.14 feet, which matches the outlet of the existing tide gate on Union Slough.

A third 36-inch diameter culvert connects the West Tidal Channel to the drainage pond. The culvert has an upstream and downstream invert elevation of -2.14 and will have a flap gate to prevent backflow from the pond into the West Tidal Channel.

A generic end-section entry loss coefficient of 0.5 has been assumed for all culverts. An average loss coefficient of zero has been assumed since the culverts will not include internal bends or reductions. An exit loss coefficient of 1.0 has been assumed for the culvert that connects the West Tidal Channel to the storage pond. An exit loss coefficient of 17 has been used to account for head losses due to the tide gates on the two outlet culverts. A duckbill-style tide gate is preferred, which has a linear discharge-head loss relationship according to the manufacturer's product information (Appendix D). An exit loss coefficient of 17 provides a comparable calculation of head loss for low

Section 4—Drainage Analysis Methods

Continued

discharge rates and a conservative calculation of head loss for larger discharge rates. The modeled tide gate head loss was compared to manufacturer's tide gate head loss data and the exit loss coefficient was evaluated by performing a sensitivity analysis (Appendix D).

Tidal Data

Simulated conditions for Union Slough were entered into SWMM as a tailwater condition time series to model the drainage system draining only during periods when the head of the system exceeds the stage on the tidally-influenced Union Slough.

Stage data collected for the Everett Riverfront Project and stage data from the Everett Water Pollution Control Facility (WPCF) were evaluated for use in these analyses. The stage data from the Everett Riverfront Project was collected during water year (WY) 2009 from the Snohomish River and provided by Snohomish County, and used by others for the Smith Island Estuary Restoration project (TetraTech, 2013A and GeoEngineers/WEST Consultants, 2011). The WPCF gage is located downstream of the Everett Riverfront Project on the Snohomish River, and the stage data was provided by the City of Everett for 2007-2013. The two sets of stage data from the Snohomish River and data from the National Oceanic and Atmosphere Administration (NOAA) Seattle, WA gage (9447130) were compared for the overlapping time period of the data sets during WY 2009. The stage data collected from the Everett Riverfront Project on the Snohomish River was consistent with the NOAA data collected on Puget Sound during tidal fluctuation and high tide periods, with the stage on the Snohomish River higher during low tides when base flow is prevalent as well as during large river flows such as the January 2009 storm event. The WPCF stage data was consistently higher than the other two by a varying amount, which may be due to datum conversion but was not able to be confirmed, and the January 2009 event was not captured in the WPCF data. The Snohomish River stage data from the Everett Riverfront project was selected based on the consistency of the high tide with the independent NOAA gage, and the higher stages due to river flow from rainfall and snowmelt.

The Snohomish River stage data from the Everett Riverfront project was repeated for each water year in the SWMM simulation to represent the tidal and river flow cycle on Union Slough. The January 2009 flood event is approximated as a 15-year return period event on the Snohomish River (TetraTech, May 2013B) and this event is repeated each January in the simulation, which provides a conservative estimate of the ability of the drainage pond to drain. The tidal statistics of the WY 2009 Snohomish River stage data was compared to nearby NOAA stations, and the use of the Snohomish River stage data results in higher tidal statistics (Appendix E).

Groundwater Seepage

Groundwater seepage rates into the West Tidal Channel and the proposed drainage pond were estimated by Shannon and Wilson (October 2013, Appendix F) by modeling the proposed site conditions in MODFLOW, and the seepage rates are included as inflow into the SWMM model to represent subsurface flow. Seepage rates were determined for both a typical fluctuating tidal condition and a flood-stage condition. The West Tidal Channel is expected to receive a base tidal seepage inflow rate of 0.048 cfs and maximum seepage rate of 0.128 cfs during flood events. The drainage pond is expected to receive a base tidal seepage inflow of 0.142 cfs and maximum seepage

Section 4—Drainage Analysis Methods

Continued

rate of 0.383 cfs during flood events. These seepage rates were added directly to each time step of the WWHM runoff time series for both the West Tidal Channel and Pond. The flood seepage rate was used when the stage in the Union Slough tidal time series exceeded an elevation of 10.0 feet, which was selected because it is above the mean higher high water elevation of approximately 9 feet but provides a conservative assumption of flood level seepage rates at stages which may correspond to high tides or high stage due to significant river flow.

Pump

The proposed pump station was modeled in SWMM using a pump link element. The pump element was defined as having a constant discharge, either 2 cfs or 4 cfs, regardless of Union Slough tidal stage. The pump float elevations were set so that the pump turned on when the water surface elevation in the pond exceeded -0.6 and switched off when the water surface elevation was drawn down to -1.0.

Modeled Scenarios

Four drainage alternative scenarios are investigated: 1) the drainage pond with one gravity outlet, 2) the proposed pond with two gravity outlets, 3) the drainage pond with a pump station with a total outflow of two cfs and two gravity outlets, and 4) the pond with a pump station with a total outflow of four cfs and two gravity outlets. Each scenario uses the same sub-basins, modeled inflow runoff and characteristics for the West Tidal Channel, proposed drainage pond, and culvert connecting the channel to the pond, and gravity outlet characteristics (size and invert). Groundwater seepage and Union Slough tide stage are the same in all scenarios. In addition, a sensitivity analysis of the tide gate head loss coefficients was performed to determine the effect of the model assumptions and tide gate on the modeled water surface elevations and discharges from the drainage pond.

The WWHM runoff volumes from the 100-year or larger flood event were also modeled in SWMM. The December 1996 event was modeled using the original simulated stage in Union Slough, and also modeled by assuming a seven-day period of flood conditions on Union Slough when the drainage pond would not drain by gravity and flood-level seepage rates. The start of the simulated seven days of flood conditions on Union Slough precedes the December 1996 rainfall event by approximately two days to model a partially-filled pond condition at the start of rainfall as a conservative assumption. The peak water surface elevations for this flood event over the seven-day duration were evaluated for 1) the two tide gate and 2) the pump station with two tide gate alternatives.

Section 5—Drainage Analysis Results

Drainage Basin Analysis and WWHM Results

The drainage areas measured from the proposed conditions sub-basin delineation are shown in Table 1, and a summary of the peak discharge rates from the hydrologic analysis of the study area under the proposed conditions are given in Table 2. A summary of modeled results from WWHM for the 1948-2009 simulation period are provided in Appendix F.

The December 1996 rainfall depths recorded by the National Weather Service were found to be larger than the 100-year rainfall depths over a 24-hour period, and over a 4-day period, and comparable to 100-year rainfall depths over a 2-day and 7-day period (Table 3). The December 1996 rainfall data was the event of record for the gage and was used to represent 100-year or larger flood conditions within the study area. The simulated runoff volumes and peak discharges entering the West Tidal Channel and drainage pond for the December 1996 rainfall event are shown in Table 4. The peak discharge rate of 28.7 cfs entering the West Tidal Channel modeled during the December 1996 event is higher than the 100-year peak discharge of 25.6 cfs estimated by WWHM, which may be attributed to the different methods of estimating return period peak discharges by using a Log-Pearson Type III distribution compared to modeled outflow which is based on HSPF calculations.

SWMM Results

Tide Gate Loss Coefficient Sensitivity Analysis

A sensitivity analysis was performed to determine the effect of the exit loss coefficient for the culverts with tide gates on the modeled water surface elevations. The SWMM model uses a constant exit loss coefficient when calculating discharge from the culverts. The manufacturer of the duck-bill type tide gate provided head loss data that is linear relative to discharge rates under submerged conditions (Appendix D), and the coefficient for head loss is therefore higher at low discharge rates and decreases with greater discharge rates. An initial SWMM simulation with a exit loss coefficient of 5.5 provided an initial range of discharge rates from the culverts of the drainage pond. The 5th, 50th, and 95th percentile peak discharge rates from the initial SWMM simulation were selected to calculate head loss coefficients from the manufacturer's data and perform the sensitivity analysis. The 5th, 50th, and 95th percentile corresponded to approximately a 2 cfs, 4 cfs, and 7 cfs respectively. The head loss coefficients calculated for the discharges from the manufacturer's data corresponded to 61, 31, and 17 respectively. A comparison of the use of a constant head loss coefficient with the manufacturer's data demonstrates that the error in head loss is relatively small at low discharges, but is can produce significant error at large discharges by using a head loss coefficient that is too high. Based on the sensitivity analysis, the head loss coefficient for the tide gate was selected as 17.0 because it provided reasonable head losses for the range of discharges expected from the culverts, without significantly over-estimating head loss during the largest discharge rates.

Water Surface Elevations

The modeled results indicate that the peak water surface elevations for the simulation period of 1948-2009 occur during the December 1996 event, with the water surface reaching 2.21 and 1.66 feet for the one and two gravity pipe alternatives, respectively, while the pump systems maintain peak water surface elevations at 0.91 and 0.49 feet for the 2 cfs and 4 cfs pump station outflow, respectively (Table 5, Appendix G). The peak water surface elevations are below the adjacent ground surface elevation of approximately 4 feet, indicating that the tidal channel and drainage pond system do not overtop during the 60-year simulation even for the one tide gate alternative. The daily exceedance for the water surface elevations indicates the percent of days during the simulation where the water surface reaches a level higher than the elevation. Any day where the elevation is

Section 5— Drainage Analysis Results Continued

exceeded is counted in the analysis, whether the elevation was exceeded for minutes or several hours.

A comparison of the exceedance frequency for the water surface elevations within the West Tidal Channel for the drainage system design alternatives indicates that the two pipe gravity system reduces the frequency of days with peak water surface elevations above -0.6 feet from approximately 70 percent with a one pipe system to 30 percent with a two pipe system, including seepage rates (Figure 5, Appendix I). The addition of a pump system with 2 cfs outflow shows that the water surface elevation is maintained at or below the -0.6 feet drain tile invert elevation for the frequent storm events and the drain tile invert is exceeded during the largest flood events. The additional outflow of a 4 cfs pump system drains the pond faster for the more frequent storm events, and only shows a significant benefit over the 2 cfs pump capacity for the largest flood events such as the December 1996 flood event.

The results from modeling the December 1996 rainfall event with seven days of flood conditions on Union Slough indicate that water surface elevations would not overtop the drainage pond or West Tidal Channel with a two tide gate gravity system and no pump station, but would inundate the tile drains for an extended time (Table 6, Appendix H). The use of a pump station with a 2 cfs total outflow reduces peak water surface elevations by about two feet compared to the two tide gate system and significantly reduces the duration that water levels exceed the tile drains following the seven-day flood conditions.

Table 5. Comparison of peak water surface elevations for the simulated period from 1948-2009 for the drainage system design alternatives.

Total Pump "On" Events	-	4
Total Pump Time (hours)	-	386

Conclusions

The hydrologic and hydraulic analysis of the study area indicates that the use of a two tide gate system reduces water surface elevations within the West Tidal Channel and drainage pond by a significant amount (reducing the frequency of days above a tile drain invert from approximately 70 percent to 30 percent). Based on conservative assumptions of seepage rates from high groundwater conditions, saturated soil conditions, the potential for runoff to flow from the west ditch to the West Tidal Channel, and high stage levels on Union Slough, a pump station will be required for water surface elevations to be maintained below the drain tile inverts (represented as - 0.6 feet in elevation) currently serving the adjacent tree nursery property.

The water surface elevations can be managed when a pump system with a total output of two cfs is operated as a contingency measure. The simulation indicates that when the pump is set to turn on when water surface elevations are near the tile drain inverts, the two cfs flow rate provides the capacity necessary to maintain surface water below the tile drains for most events except for the largest flood events such as the December 1996 event. The use of a four cfs capacity pump system (such as two, 2 cfs pumps) drains the pond faster and maintains a lower peak water surface elevation in the channel during the large flood events, but does not provide significant benefit for the more frequent conditions.

Appendix B

Photo Documentation

Photo B-1. The West Tidal Channel looking South from approximately Station 33+00 of the proposed setback dike in February 2013.

Photo B-2. The West Tidal Channel at the same location as Photo 1 in May of 2013.

Appendix B

Photo Documentation

Photo B-3. The West Tidal Channel at the same location as Photos B-1 and B-2 in September of 2013.

Photo B-4. The east-west agricultural ditch connecting the West Tidal Channel and East Tidal Channel with 12" pipes connection at either end, looking east.

Appendix B

Photo Documentation

Photo B-5. Tile drain outlets in the West Tidal Channel in June 2013. The tile drain with invert -1.71 feet is sediment-colored at the bottom of the staff, while the tile drain with invert elevation -0.07 feet is the green PVC pipe.

Appendix C. Tidal Channel, Drainage Pond, and Depression Storage Calculations

Table C-I. Depression storage calculated within sub-basin P5 to determine approximate runoff volumes and elevations required for stormwater to drain north to the West Tidal Channel..

Elevation (NAVD88)	Storage (ac-ft)
1.5	0.00
2	0.01
2.5	0.02
3	0.04
3.5	0.29
3.8	1.01
4	1.49
4.5	4.08
5	8.70

Appendix C.

Table C-2. Stage-storage relationship developed for the section of the West Tidal Channel connected to the drainage pond with a 10% reduction in storage assumed.

Stage (NAVD88 Feet)	Storage Volume (ac-ft)	Volume - 10% Loss of Storage (ac-ft)	Equivalent Area (ac)
-4.50	0.00	0.00	0.00
-4.00	0.04	0.03	0.11
-3.50	0.29	0.26	0.62
-3.00	0.82	0.74	1.04
-2.50	1.57	1.42	1.50
-2.00	2.59	2.33	1.91
-1.50	3.80	3.42	2.26
-1.00	5.16	4.64	2.51
-0.50	6.65	5.98	2.73
0.00	8.23	7.41	2.89
0.50	9.90	8.91	3.04
1.00	11.66	10.49	3.21
1.50	13.50	12.15	3.36
2.00	15.44	13.89	3.52
2.50	17.46	15.71	3.67
3.00	19.56	17.61	3.84
3.50	21.88	19.69	4.15
4.00	24.32	21.88	4.48

Table C-3. Stage-storage relationship developed for the drainage pond with a 5% reduction in storage assumed.

Stage (NAVD88 Feet)	Storage Volume (ac-ft)	Volume - 5% Loss of Storage (ac-ft)	Equivalent Area (ac)
-3.14	0.00	0.00	6.68
-3.00	0.99	0.94	6.68
-2.00	8.13	7.72	6.78
-1.00	15.44	14.67	6.95
0.00	22.94	21.79	7.12
1.00	30.61	29.08	7.29
2.00	38.46	36.53	7.46
3.00	46.48	44.16	7.63
4.00	54.69	51.95	7.79

Appendix D. Tide Gate Head Loss Data and Sensitivity Analysis

Appendix D.

Figure D-1. Manufacturer's Head loss data.

Discharge-Head Loss Comparison

Smith Island Estuary Restoration
September 27, 2013

Figure D-2. Comparison of head loss to discharge for varying loss coefficients and the manufacturer's data.

Tide Gate Exit Loss Sensitivity Analysis

Tide Gate Discharge-Frequency

Smith Island Estuary Restoration
September 26, 2013

Figure D-3. Sensitivity of modeled discharge exceedance frequencies for each tide gate to varying head loss coefficients.

Appendix E. Tide Station Comparison

Statistics for the tide stations in Seattle (National Oceanic and Atmospheric Administration (NOAA) Station (9447130, Verified data), Everett (9447659, predicted tide), Marysville (9447729, predicted tide), and Port Townsend (9444900, Verified data) are compared to the Snohomish River (WY 2009) stage data used for Union Slough (Table E-1). Verified stage indicates the data was quality controlled by NOAA; predicted indicates the results of a tide stage model, used when no verified data exists for the period of record.

Table E-1. Comparison of Tidal Statistics of the Snohomish River stage data to NOAA stations.

	Water Surface Elevation (feet NAVD88)				
	Seattle	Everett	Marysville	Port Townsend	Snohomish River (WY 2009)
MHHW	9.02	9.06	9.17	7.41	9.21
MHW	8.15	8.18	8.3	6.73	
MTL	4.32	4.48		4.06	4.80
MLW	0.49	0.77		1.39	
MLLW	-2.34	-2.03		-1.11	-1.02

The tide statistics calculated for the Snohomish River WY 2009 stage data selected for SWMM modeling are higher than the statistics calculated than the NOAA stations, and represents a conservative estimate of tidal stage.

The Seattle District U.S. Army Corps of Engineers (USACE) conducted a tidal surge analysis for the Snohomish River in 2000 that established tide elevations used for the calibration of the downstream boundary conditions for the FEMA Flood Insurance Study on the Snohomish River (Table E-2) (WEST, 2001).

Table E-2: USACE Snohomish River Tidal Surge Elevations.

	Snohomish River Stage	
	Elevation (feet NGVD)	Elevation (feet NAVD88)
500-year	8.7	12.38
100-year	8.4	12.08
50-year	8.2	11.88
10-year	7.8	11.48
MHHW	5.2	8.88

The exceedance frequency for the simulated stage on Union Slough based on the selected Snohomish River stage data is shown in Figure E-1.

Appendix E.

Figure E-1. Hourly percent exceedance for stage levels in the selected stage data set for WY 2009.
